---

Cognitive Psychology

### What is attention?

- Humans don't process all incoming sensory stimulation that is available
- Human information processing starts very early by seeking out, focusing, and selecting particular aspects of the available information
- Attention is the mechanism by which we restrict information processing to only a small fraction of the possible amount of information
- Attention includes both conscious processes and unconscious processes
- Often cognitive processes (such as object identification) are the end result of unconscious processing (visual grouping processes)

---

---

---

---

---

---

---

Cognitive Psychology

### Different views on attention

- **Vigilance and signal detection**
  - Waiting for one's luggage at the airport...
- **Selective attention**
  - Listening to a conversation at a party...
- **Divided attention**
  - Listening to a second conversation while still pretending to be engaged in the first one...
- **Search**
  - Searching for one's car in the parking lot...

University of Idaho © Steffen Werner - 2004 Perception.13. 3

---

---

---

---

---

---

---

---

**Cognitive Psychology** **Vigilance**

- **Vigilance refers to the ability to attend to a situation for an extended period of time**
  - The goal usually is the detection of "something" (more technically "a sensory event" or "signal")
- **Human performance**
  - Performance decreases with increasing time
  - Decrease can be due to
    - Loss of sensitivity (sensory adaptation)
    - Drifting attention (sometimes due to habituation)
    - Criterion changes (see signal detection theory)
- **Problem of fatigue**
  - Availability of frequent rest periods important

---

---

---

---

---

---

---

---

---

---

---

---

**Cognitive Psychology** **Why is vigilance important? Plant operator**

University of Idaho © Steffen Werner - 2004 Perception.13. 5

---

---

---

---

---

---

---

---

---

---

---

---

**Cognitive Psychology** **Why is this important?**

**This is a classic example of signal detection...**

University of Idaho © Steffen Werner - 2004 Perception.13. 6

---

---

---

---

---

---

---

---

---

---

---

---

**Cognitive Psychology** **Signal detection theory (SDT)**

- Perception can be viewed as decision making under uncertainty
  - "Is that smoke over there, or just a cloud ...?"
- What we "decide" to perceive is based partially on the following
  - The strength of the perceptual event (signal)
  - The amount of background events (noise)
  - A subjective threshold of the relative strength of signal to noise (criterion)
  - The benefits of detecting a signal vs. the costs of not detecting it or falsely detecting it
  - Expectancies (base rates - how likely is this?)
  - Selective attention

University of Idaho © Steffen Werner - 2004 Perception.13. 7

---

---

---

---

---

---

---

---

---

---

**Cognitive Psychology** **Correct vs. false responses in SDT**

	<b>observers reaction</b>	<b>report signal</b> "fire!"	<b>report no signal</b> "no fire"
<b>real world</b>			
<b>signal present</b>	<i>fire is starting</i>	<b>hit</b> \$1,000	<b>miss</b> \$100,000
<b>signal absent</b>	<i>nothing</i>	<b>false alarm</b> \$500	<b>correct rejection</b> \$0

University of Idaho © Steffen Werner - 2004 Perception.13. 8

---

---

---

---

---

---

---

---

---

---

**Cognitive Psychology** **Correct vs. false responses in SDT**

	<b>observers reaction</b>	<b>report signal</b> "guilty!"	<b>report no signal</b> "not guilty"
<b>real world</b>			
<b>signal present</b>	<i>person is guilty</i>	<b>hit</b> good	<b>miss</b> bad
<b>signal absent</b>	<i>person not guilty</i>	<b>false alarm</b> very bad	<b>correct rejection</b> good

---

---

William James (1890)

[Attention] is the taking possession of the mind, in clear and vivid form, of one out of what seem several simultaneously possible objects or trains of thoughts.

... It implies withdrawal from some things in order to deal effectively with others.

---

---

---

---

---

---

---

---

● An example for selective attention

---

---

---

---

---

---

---

---

- People can attend selectively to particular events or objects
- Cherry was the first to systematically investigate how humans attend to one of two simultaneous acoustical events
- His studies showed that...
  - Participants knew little about the content, language, well-formedness, etc. of the unattended message
  - Did notice gross features of the speakers (male / female, differences in tone of voice)
- We will revisit this phenomenon again in the next modules

---

---

---

---

---

---

---

---

**Cognitive Psychology** **Divided attention**

- **People can perform more than one task at a time (multi-tasking)**
  - Driving and reading billboards
  - Walking and chatting with a friend
  - Listening to a web-lecture and watching tv (we will see soon how well this might work;-)
- **Attentional resources can be allocated to different tasks depending on the processing needs**
  - When driving on an icy road, the driver doesn't read the billboards any more
- **Attentional resources are limited**
  - Tasks demand different amounts of attention

University of Idaho © Steffen Werner - 2004 Perception.13. 13

---

---

---

---

---

---

---

---

---

---

**Cognitive Psychology** **Controlled vs. automatic processing**

- **Cognitive processes can be differentiated based on the amount of cognitive control they require**
  - Tying shoe laces vs. imagining to walk home
  - Routine tasks vs. solving new problems
  - Continuum: total control to totally automatic
- **Learning, automatization, proceduralization**
  - Most tasks require less control after practice
  - Separate steps are integrated into one
  - Information is processed in larger units
  - Less step-by-step verification

University of Idaho © Steffen Werner - 2004 Perception.13. 14

---

---

---

---

---

---

---

---

---

---

**Cognitive Psychology** **Controlled vs. automatic processing**

Characteristic	Controlled	Automatic
<b>Effort</b>	Intentional	No effort
<b>Conscious</b>	Fully available	Usually not
<b>Resources req.</b>	Large demand	Negligible
<b>Type of processing</b>	Serially	Parallel
<b>Speed</b>	Slow	fast
<b>Flexibility</b>	High	Low
<b>Level of processing</b>	High (analysis)	Low
<b>Difficulty</b>	Variable	Variable

University of Idaho © Steffen Werner - 2004 Perception.13. 15

---

---

---

---

---

---

---

---

---

---

**Cognitive Psychology** The "limited attentional resources" view

- **The cognitive system has limited resources**
  - One general resource
  - Multiple (modality-)specific resources
- **Attentional processes require resources**
  - Each process uses up part of the resources
  - Processes compete for resources
  - Automatization reduces the amount of resources needed to perform the task
- **Divided attention**
  - Multiple attention demanding processes can be active at the same time as long as they don't require all of the resources

University of Idaho © Steffen Werner - 2004 Perception.13. 16

---

---

---

---

---

---

---

---

---

---

**Cognitive Psychology** Examples of automatization

- **Divided attention: Dual tasks** (Spelke, Hirst & Neisser, 1976)
  - Practicing reading for comprehension and writing down dictated words
  - Practice both tasks 5 days a week (85 sessions)
- **Performance**
  - In line with expectations, participants were much worse at performing both tasks simultaneously than in isolation
  - After enough practice, this difference vanished
  - Even when semantic categorization was required for dictated words, performance bounced back to normal performance in the dual task

University of Idaho © Steffen Werner - 2004 Perception.13. 17

---

---

---

---

---

---

---

---

---

---

**Cognitive Psychology** The risks of automatization: Classification of slips (James Reason, 1990)

- **Capture error:**
  - automatic process takes over even though a deviation was planned
- **Omission/perseveration:**
  - because of an interruption steps are missed or repeated
- **Data-driven errors:**
  - Sensory information initiates / modifies the planned action
- **Loss-of-activation error:**
  - After the initiation of an action important information is lost (what am I doing?)
